Connectionist and Statistical Language Processing

Lecture 4: Pattern Associators and Competitive Networks

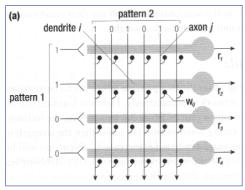

Matthew W Crocker

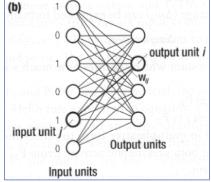

Computerlinguistik Universität des Saarlandes

Overview ■ Learning: ☐ The delta rule + The perceptron convergence rule ♣ Gradient descent learning ☐ Back-propagation of error with hidden-layers + The Generalized Delta Rule + Not generally views as biologically plausible ■ Pattern Associators: 2-layer networks Networks as matrices ■ Associating distributed representations Hebbian learning ☐ Generalisation in learning ■ Biological plausibility Competitive networks and unsupervised learning © Matthew W. Crocker Connectionist and Statistical Language Processing

Pattern Associators

- Learn to associate one stimulus with another, e.g.:
 - ☐ Sight of chocolate associates with taste of chocolate
 - ☐ The string "yacht" associates with the pronunciation /y/ /o/ /t/
 - ☐ Etc.

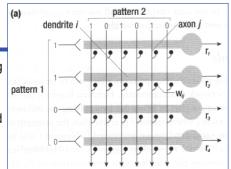

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Learning: Hebb's rule

- The idea behind Hebbian learning is simple:
- The two patterns to be associated are presented simultaneously

- \blacksquare If there is activity on input axon j, when neuron i is active, then the connection weight w_{ii} (between axon j and dendrite i)is increased

$$lacktriangle$$
 The Hebb rule: $\Delta w_{ij} = \varepsilon a_i a_j$

- \Box a_i is the activity of element *i* in P₁
- \square a_i is the activity of element j in P₂
- \square ϵ is the learning rate parameter

© Matthew W. Crocker

Connectionist and Statistical Language Processing

An example

- Assume binary neuron activations (0 or 1)
- Suppose the sight of chocolate is represented as: (1 0 1 0 1 0)
- The taste of chocolate is represented as (1 1 0 0)
- We can represent the weights as a 6x4 matrix of "synapses"

Weights *before* learning:

	1	0	1	0	1	0
	\downarrow	\downarrow	\downarrow	\downarrow	\downarrow	\downarrow
•	0	0	0	0	0	0

Weights after learning:

		1	0	1	0	1	0
		\downarrow	\downarrow	\downarrow	\downarrow	\downarrow	\downarrow
1	\rightarrow	1	0	1	0	1	0
1	\rightarrow	1	0	1	0	1	0
0	\rightarrow	0	0	0	0	0	0
Ο	\rightarrow	Ο	Ο	Ο	Ο	Ο	Ο

Assume that ε =1

Recall from a Trained Matrix

- Netinput_i = $\sum_i a_i w_{ii}$
- This is just the *dot product* of 2 vectors, i.e.:

$$(1\ 0\ 1\ 0\ 1\ 0)$$
 $(1\ 0\ 1\ 0\ 1\ 0)$

$$= (1 \times 1 + 0 \times 0 + 1 \times 1 + 0 \times 0 + 1 \times 1 + 0 \times 0) = 3$$

- Thus for the recall cue (1 0 1 0 1 0), the output pattern is:

 - 0 0 0 0 0 0
 - 0 0 0 0 0
- If we assume a threshold of 2, where values <2 are 0 and others are 1:
 - ☐ Then the output pattern of activity is (1 1 0 0)

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Learning Multiple Associations

- It is not very "computationally" surprising that an array of 24 can store the relationship between two vectors of size 6 and 4 respectively
- What happens if we try to store different associations with the same weight matrix?
 - ☐ Appearance of apricots: (1 1 0 0 0 1)
 - ☐ Taste of apricots: (0 1 0 1)

Change in weights for apricots:

The combined weight matrix:

0 1

1

		1	1	0	0	0	1	
		\downarrow	\downarrow	\downarrow	\downarrow	\downarrow	\downarrow	
0	\rightarrow	0	0	0	0	0	0	
1	\rightarrow	1	1	0	0	0	1	
0	\rightarrow	0	0	0	0	0	0	
1	\rightarrow	1	1	0	0	0	1

Recall of multiple associations

- We can now see how well the pattern associator can perform recall for the 2 patterns
- Assume a threshold of 2
- Apricots:
 - □ Netinput: (1 4 0 3)
 - □ Output: (0 1 0 1)
- Chocolate:
 - □ Netinput: (3 4 0 1)
 - □ Output: (1 1 0 0)
- Both are correctly recalled

- 1 1 0 0 0 1
- 1 0 1 0 1 0 → 1
- $2 \ 1 \ 1 \ 0 \ 1 \ 1 \rightarrow 2$

- 1 0 1 0 1 0
- 1 0 1 0 1 0 →
- $2 \quad 1 \quad 1 \quad 0 \quad 1 \quad 1 \quad \rightarrow \quad 4$
- 1 1 0 0 0 1 →

Recall, Similarity and Linear Algebra

- We have seen so far how network behaviour can be understood in terms of vectors, matrices, and operations thereon.
 - ☐ If an input pattern **a**, and the weights **w** leading from the inputs to some node are represented as vectors. Netinput to that node is the *dot product*.

netinput_i =
$$\sum_{j} a_{j} w_{ij}$$
 = **a• w**

- ☐ If the current weights are represented by a matrix **m1**, and the change in weights by a matrix **m2**, then the new weight matrix is simply: **m1** + **m2**
- Observe: the dot product is highest when two vectors are *similar*.
 - □ Numbers in vector 1 are similar to those in the *corresponding positions* in vector 2
 - ☐ Thus netinput is highest for similar input/weights
 - ☐ Each dissimilarity reduces the netinput
 - ☐ Vectors with a dot product of 0 are said to be orthogonal

.

Properties of Pattern Associators

Similarity in vectors

□ p: 10000111

 \square w₁: 10000111 =

 \square w₂: 10001011 = 3

 \square w₃: 0 0 1 1 1 0 1 1 = 2

 \square $W_4: 0 1 1 1 1 0 0 0 = 0$

- Operation of pattern associators using the Hebb rule:
 - \square Learning: if a neuron i is activated by P_1 , an increment Δw_i that has the same pattern as P_2 , is added to the weight vector of neuron i.
 - □ Recall:since patterns presented during learning are directly reflected in the weight vector for neuron *i* , the output at neuron *i* reflects the similarity of the recall cue to patterns presented during learning
- Properties
 - Generalisation
 - □ Fault tolerance
 - □ Prototype extraction
 - ☐ Speed

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Generalisation

- If a presented cue is similar to one that is learned, a pattern associator will often produce a similar response for the new as for the old pattern
 - ☐ This means networks can associate "imperfect/noisy" stimuli
- I.e. Insensitive to relatively small differences in input stimuli:
 - □ E.g. (1 1 0 1 0 0) is slightly different from (1 1 0 0 0 1)
 - ☐ Or, (1 0 1 0 0 0) is slightly different from (1 0 1 0 1 0)

```

11

Fault tolerance

- Just as pattern associators can often deal with imperfect stimuli, they are often robust to damaged connections (synapses)
- This is because PAs compute a correlation of the pattern with the weights via a relatively large number of axons

■ This can help explain continued (sometime partial) function in the event of normal cell loss, or certain kind of (distributed) brain damage.

© Matthew W. Crocker

Connectionist and Statistical Language Processing

More Properties

- Prototype Extraction & Noise Reduction
 - ☐ If the network is exposed to similar (but slightly different) P2s for a given P1 during training, the (scaled) weight vectors becomes the *average*
 - ☐ When tested, the best response is to the average patter vector
 - ☐ Thus, even if trained on noisy instances, the network will have learned to respond to a prototype (which is has never explicitly seen).
- Interference
 - ☐ Not such a problem in distributed (non-local/symbolic) systems
 - ☐ Permits noise reduction, fault tolerance, generalisation, etc
 - ☐ Explains certain aspects of human memory and cognitive function
 - ☐ Robustness versus 100% accuracy
- Speed
 - □ Because computation is distributed, across multiple neurons and synapses, the response to a stimulus can be determined in 1-2 steps
- Distributed Representations are Important
 - □ Information about the stimulus is *distributed* over the population of elements, rather than encoded by a single element
 - ☐ Generalisation and graceful degradation rely on a continuous range of dot products

Connectionist and Statistical Language Processing

13

Summary of Pattern Associators

- Associate multiple stimulus-response patterns in a single network
 - ☐ Networks can be represented as a weight matrix
- Weights are sensitive to similarity
 - ☐ The more similar, the higher the netinput; the dot product of P and W
- Important properties
 - ☐ Generalisation: robust to noisy input
 - ☐ Fault tolerance: robust to loss/damage
 - Prototype extraction & noise reduction
- Biologically Plausible:
 - Learning is strictly local
 - □ Reinforcement based
- Auto Association
 - ☐ We can also train a network to associate a given pattern with itself
 - Why?
 - ♣ Noise reduction, prototype extraction
 - + = category formation (unsupervised)

Connectionist and Statistical Language Processing

Competitive Networks: Overview

- Operation:
 - ☐ Given a particular input, output units compete with each other for activation
 - ☐ The winning output unit is the one with the greatest response
- During training:
 - Connections to the winning unit from the active input units are strengthened
 - ☐ Connections from inactive units are weakened
- Training is unsupervised
 - ☐ The is no external teacher
 - ☐ The network will categorise inputs, based on similarity

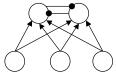

© Matthew W. Crocker

Connectionist and Statistical Language Processing

15

Architecture of Competitive Networks

- A simple network:
 - ☐ Inputs are fully connected to outputs by feed-forword connections
 - Outputs may be connected to each other by *inhibitory* connections

- Outputs compete until only one remains active
 - Or, simply the unit with highest activation wins
- **Excitation of outputs:** $\operatorname{netinput}_i = \sum_j a_j w_{ij}$
 - Dot product of input activations and the weight vector the the output
- Competition:
 - Output activations are compared, unit with highest activation wins
 - ☐ Or, direct competition among outputs, via inhibitory connections:
 - + Active units force other units to become inactive

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Adjusting Weights

Weights are only adjusted on connections feeding into the winning output node:

$$\Delta w_{ij} = 0$$
 if unit *i* loses
= $\epsilon (a_i w_{ii})$ if unit *i* wins

- Where,
 - ϵ is the learning rate parameter
 - a_i is the activity of input unit j for pattern p
 - w_{ij} is the weight of the connection from j to i before the trial
- Behaviour
 - ☐ The strengths of connections to the winning unit are adjusted until each weight is the same as the activity of its input
- Result
 - ☐ The winning unit's weight vector is changed to make is more similar to the input vector for which it is the winner

© Matthew W. Crocker

Connectionist and Statistical Language Processing

17

An example

Consider the following network:

■ Input pattern: (0 1 1)

$$netinput_3 = (0x0.3+1x0.2+1x0.5)$$

$$= 0.7$$

$$netinput_4 = (0x0.2+1x0.3+1x0.5)$$

= 0.8

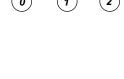

- Since, unit₄ wins:
 - ☐ No changes in connections to unit₃
- For connections to unit₄:

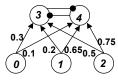

$$\Box \Delta w_{ii} = \varepsilon (a_i - w_{ii})$$

$$\triangle w_{ii} = 0.5 (0-0.2 \ 1-0.3 \ 1-0.5)$$

$$\triangle W_{ii} = 0.5 (-0.2 \ 0.7 \ 0.5)$$

$$\triangle \Delta W_{ii} = (-0.1 \ 0.35 \ 0.25)$$

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Overall behaviour

- Netinput to an output unit is greatest when it's weight vector is most similar to the input vector
- Training makes the weight vector for a particular winning unit more similar to the input pattern
- It is therefore also likely to be the "winning unit" for similar patterns, and therefore learn to respond to those patterns as well
- The weight vector for a particular output unit learns to respond to similar input patterns
 - ☐ Because these patterns are all slightly different, the learned weights cannot exactly mimic the associated inputs
 - □ Rather, the learned weights will be an average of the patterns, based on the frequency of presentation during training
- The competitive network can therefore learn to categorise similar inputs without any "teacher": unsupervised learning

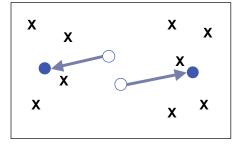

© Matthew W. Crocker

Connectionist and Statistical Language Processing

19

Visualising competitive learning

- Represent input patterns & weight vectors in multi-dimensional space
 - weight vectors for the output units have a random relation to the input patterns
 - ☐ Competitive learning changes the weight vector for a particular output so that it becomes the average for a subset of inputs
 - ☐ More outputs enable the network to more finely categorise the inputs

© Matthew W. Crocker

Connectionist and Statistical Language Processing

More on competitive networks

- Weight growth:
 - Depending on how training occurs, if many similar patterns are associated with one output, it may be impossible to other outputs to ever gain more activation, even for quite different input patterns
 - ☐ We could limit weight growth, by insisting that the sum of a weight vector equal some constant, and learning could only redistribute weight among connections to the winning unit
- As with Hebbian networks, learning is local:
 - Winner is found by competition of output: inhibitory connections leave only one neuron firing
 - ☐ Hebbian learning means that only connection weights to this node are changed
 - ☐ Information is available at the axon and dendrite of a connection
 - ☐ Also: no explicit teacher is required
- Remove redundancy: set of inputs associated with a single output
 - ☐ Sparsification: convert pattern stimuli to a localist representation
- Outputs are less correlated (possibly orthogonal) than inputs:
 - ☐ Useful as input to pattern associators (easier to learn less correlated patterns)

© Matthew W. Crocker

Connectionist and Statistical Language Processing

21

An example: Pattern classification

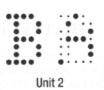

- We can use an unsupervised network to classify patterns of letters
- Input is a 7 x14 "retina", connected to 2 outputs each with a 98 element weight vector, which is trained on pairs of letters:

- First the network is trained on pairs of letters: AA, AB, BA, BB
- The resulting weights to the outputs are as follows:
 - ☐ Unit 1: AA, AB
 - ☐ Unit 2: BA, BB
- Why? What else could it learn?
- What would happen if the network had 4 output units?

Unit 1

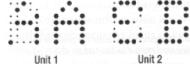

© Matthew W. Crocker

Connectionist and Statistical Language Processing

Pattern classification continued

- Consider the case where we train the network on individual letters, instead of pairs: A, B, E, S
- Cluster using 2 output units
- The result will be to cluster A & E and B & S, since they are the most similar: thus the classifier acts as a feature detector within letters
- What if the network is trained to classify AA, BA, SB, EB
 - ☐ As we would expect, the network learns a letter specific classification
 - ☐ But, we have forced A & B and S & E to be grouped together
 - ☐ In this way, we force the network to find whatever features do *correlate* for the letters in the 1 position
 - The 2nd letter acts as a teacher, since it forces the network into a specific solution
